

Visipoint Add Visit Load Test — Bug Report

Test date:	2026-08-03
Test type:	Load test — 1000 concurrent virtual users, 30s ramp-up, single account, Login → Add Visit (expected-visit) per user
Tool:	Apache JMeter 5.6.3
Test plan:	D:\apache-jmeter-5.6.3\visipoint-project\visipoint-addvisit-load-test.jmx
Raw results:	addvisit-results.jtl
Tester:	Claude (JMeter load test, built from a real captured Add Visit request; user executed the run)

Summary Results

Step	Success	Failed	Avg	P50	P95	P99	Max
Login	844/1000 (84.4%)	156 (15.6%)	32.7s	24.2s	86.1s	103.3s	195.9s
Add Visit	0/1000 (0%)	1000 (100%)	5.8s	0.4s	25.7s	53.8s	231.7s

BUG-PERF-004 — Add Visit fails 100% of the time, same session-invalidation root cause as Logout (BUG-PERF-001) and Add User (BUG-PERF-003) — now confirmed on a THIRD independent endpoint

Module	Add Visits — Add Expected Visitor / Authentication session management
Endpoint	POST <code>https://api.visipoint.uk/api/expected-visit</code> (session via POST <code>https://api.visipoint.me/api/login</code>)
Severity	High — same confirmed root cause, third independent confirmation
Status	New — same bug as BUG-PERF-001 / BUG-PERF-003, different endpoint

#	Step	Expected	Actual
1	Log in, then immediately call POST <code>/api/expected-visit</code> with that session's token	Request should succeed using the freshly-obtained token	0/1000 (0%) succeeded
2	Check failure breakdown	If load-related, failures should mostly be connection-level, not clean auth rejections	523/1000 (52.3%) were clean 401 <code>Unauthorized</code> — the same session-invalidation signature seen on Logout and Add User

Expected: A freshly-obtained access token should work for adding an expected visit, the same as any other authenticated action.

Actual: 100% of Add Visit calls failed. Just over half (52.3%) were the now-familiar 401 Unauthorized — this is the third distinct endpoint (after Logout and Add User) where the same session-token-invalidation bug produces a 100% or near-100% failure rate under concurrent same-account logins. This is no longer a pattern specific to one endpoint or code path — it's a property of the session/token system itself, and will affect **any** authenticated call made shortly after a competing login on the same account.

Root cause: Same as BUG-PERF-001/BUG-PERF-003 (see those reports for full detail). No new investigation needed here; this test simply adds a third confirmation point.

Secondary/unresolved finding: a different failure signature this run — DNS resolution errors

Unlike the Add User runs (clean 401s plus ordinary connection-refused/socket errors), **44.6% of Add Visit's failures (446/1000) were `UnknownHostException`** — a DNS resolution failure, not a connection or auth error. This wasn't seen in any of the three prior Add User runs.

Failure type	Count	% of Add Visit failures
401 Unauthorized (session bug)	523	52.3%
UnknownHostException (DNS failure)	446	44.6%
SocketException	16	1.6%
HttpHostConnectException	15	1.5%

This is flagged as unresolved, not attributed. A DNS resolution failure partway through a test most often points to the load-generating machine's own DNS resolver being overwhelmed by concurrent connection attempts, rather than a server-side issue — but this wasn't controlled for and shouldn't be assumed. It could also be a transient network blip unrelated to Visipoint. Recommend re-running this specific test to see whether the DNS failures reproduce consistently (load-generator-side limit) or don't recur (one-off blip) before drawing a conclusion.

Login performance (consistent with prior findings)

At 30s ramp-up, Login succeeded 84.4% of the time — in line with the 30s Add User run (79.9%) and the already-established pattern: Login degrades under a fast 30-second ramp-up due to connection contention, and fully recovers to 100% success at a 5-minute ramp-up (per the Add User test series). No new Login investigation needed; this is the same already-understood, already-resolved pacing issue.

Recommendations

1. **No new backend investigation needed for the core bug** — this is the third confirmation of BUG-PERF-001/003's root cause. Treat Logout, Add User, and Add Visit as symptoms of one bug to fix once.
2. **Re-run this specific test to check the DNS failure signature** — if it recurs consistently, it points to a load-generator-side capacity limit; if not, it was likely a one-off.

3. Same as prior reports: a distinct-accounts run would be needed for real Add Visit capacity data once the session bug is fixed.

Appendix: Test data cleanup note. This run attempted to create expected visits tagged `first_name=LOADTEST`, `last_name=LOADTEST_<threadNum>`, email pattern `loadtest+visit<threadNum>_XXXXX@lomasatech.com` — but since 100% of Add Visit calls failed, no test visit records were actually created. No cleanup needed.
